

Week 1 Summary – Python Programming Basics

Objective

The objective of Week 1 was to learn the fundamentals of Python programming and apply them by developing simple programs for data processing.

Concepts Learned

- Learned the basics of Python programming and its applications.
- Understood variables and different data types such as integers, floats, strings, and booleans.
- Performed arithmetic, comparison, and logical operations using Python operators.
- Learned how to take input from the user and display output.
- Used conditional statements (`if`, `elif`, `else`) to make decisions in programs.
- Implemented `for` and `while` loops to perform repetitive tasks.
- Created simple Python programs to strengthen programming skills.

Hands-on Programs Completed

1. Calculator
2. Temperature Converter
3. Largest of Three Numbers

Client Project

Project Title: Sales Report Generator

Project Description

Developed a Python program that accepts daily sales data for one week and generates a sales report. The program calculates:

- Total weekly sales
- Average daily sales
- Highest sales
- Lowest sales
- Best-performing sales day

Skills Used

- Variables
- Lists
- User Input
- Loops

- Conditional Statements
- Basic Data Processing
- Data Analysis

Learning Outcome

This week helped me build a strong foundation in Python programming. I gained practical experience in writing Python programs, processing user data, using loops and conditional statements, and creating a simple data analysis project. These concepts will serve as the foundation for upcoming topics in Data Science.
